Sir,

*Nocardia* is a gram-positive bacillus, which is the cause of various diseases such as cutaneous, ocular and central nervous system (CNS) infections in both immunocompetent and immune-compromised patients [1]. The range of these diseases can be from a sub-clinical infection to a life-threatening diseases [2]. These infections especially CNS infections are more happens in immunocompromised patients [1, 2]. On the other hand over the past several years the number of immunocompromised patients are increased [1]. Nocardial meningitis is very rare and may be associated with or without a brain abscess.

In this paper, we describe a man with Behçet disease who was on corticosteroid, and experienced meningitis caused by *Nocardia farcinica*.

A 38 years old man admitted with complaints of fever, nausea, vomiting, frontal headache and hemiplegia on left side and decreased level of consciousness.

On admission the patient has temperature of 40°C, his blood pressure was 190/110, pulse rate was 115 beats/min; respiratory rate was 20/min; and his oxygen saturation degree was 92%. The forces of lower limbs had been decreased to 3/5. In eyes there was horizontal nystagmus and in left eye the movement of the globe to medial and lateral sides was disturbed; but no papilledema was seen in examination of both sides.

The patient was a known case of Behçet disease since 4 years ago, and was on 20 mg prednisolone daily since that time. At first, with this primary information; vancomycin, meropenem and aciclovir, were prescribed as an antibiotic regi-

*Figure 1* Diffuse signal change as high in T2W at limited view of brain stem is seen involving pons and medulla without obvious mass effect.
According to the signs and symptoms of the patient and CSF pattern, antibiotic regimen was changed to meropenem and intravenous co-trimoxazole (to treat nocardial meningitis).

Brain magnetic resonance venography result was in normal limit and in brain magnetic resonance imaging high T2/flair signal intensity lesions were shown in medulla oblongata, pons and brain; which could be suggestive for demyelinating or vasculitis disorders (figure 1).

A few days later, CSF culture was reported positive for Nocardia species (figure 2); therefore PCR for Nocardia species was performed and the result was positive for N. farcinica. Fortunately after 10 days; the general condition of the patient became better and improvement of headache and neurological sign and symptoms were achieved. Intravenous antibiotics were continued for 6 weeks in hospital and after that the patient was discharged with oral antibiotics (cotrimoxazole, cefixime and amoxicillin-clavulanic acid) for up to 9 months. After that cotrimoxazole was continued for 3 months later. Now after one year the patient is on cotrimoxazole yet, and he has not any problem and feels completely well.

Nocardiosis is an opportunistic infection that affects mainly immune-compromised patients, especially the patients with cell-mediated immunity such as acquired immunodeficiency syndrome [3]. Neuro-Behçet’s disease (NBD), is one of the most dangerous and serious complications of the Behçet’s disease which is described in some papers [4]. One of the criteria for NBD diagnosis is “no better explanation for neurological findings” [5], and in our patient CSF smear, culture and PCR were positive for N. farcinica.

In some reports of systemic nocardial infections, CNS infection is seen in up to 44% [6]. Beaman et al. reported single-organ infection is manifested as pulmonary as the most common (39% in hospitalized patients), followed by CNS infection (9%) in nocardial infections [7]. CNS nocardial infection is an uncommon disease and carrying a high mortality rate [8]. In our cases we did not find any other site of infection in the body and therefore we concluded that “isolated meningitis” is the most probable diagnosis in this patient; which is really a rare incident. Although, isolated CNS infections, as abscesses in spinal cord and brain without extra-CNS involvement are reported [9]; but there is not any report of isolated and /or pure nocardial meningitis similar to our case. Isolated nocardial meningitis may progress to CNS abscess; therefore early diagnosis can prevent of abscess formation and the better prognosis will be achieved in these patients.

In every immune-compromised patient who has referred by CNS infection; thinking about nocardial CNS infection as a differential diagnosis would be logic.
